Mechanism design / contract theory is the design of incentive structures.

This requires:

- ◊ explaining rules/game/outcomes to agents
- ◊ interpreting the messages of the agents

Economists like to model uncertainty via state-spaces

Real communication (contracts, messages, etc) regards **statements** not states

- ◊ This is dependent of language of the decision maker
- ◊ Awareness complicates the picture
- ◊ But, what if agents speak different languages or are differentially aware?

This paper is a theory of translation

- ◊ How agents' language represents their understanding of uncertainty
- ◊ How this might be communicated between agents
- ◊ When can different agent's views be unified into a universal perspective

*Model: Languages*

A language is a bounded distributive algebra  $\mathcal{L}$  representing sets of statements that can be true or false:

- ◊  $T$  and  $F$  are distinguished elements
- ◊ closed under disjunction  $\vee$ 
  - ◊ if  $\lambda$  and  $\eta$  are statements in  $\mathcal{L}$ , then so is  $\lambda \vee \eta$
  - ◊ interpreted as OR; at least one of  $\lambda$  and  $\eta$  is true
- ◊ closed under conjunction  $\wedge$ 
  - ◊ if  $\lambda$  and  $\eta$  are statements in  $\mathcal{L}$ , then so is  $\lambda \wedge \eta$
  - ◊ interpreted as AND; both  $\lambda$  and  $\eta$  are true

Formally,  $\mathcal{L}$  must satisfy the following properties:

◊ **Commutativity**

- ◊  $\lambda \vee \eta = \eta \vee \lambda$

- ◊  $\lambda \wedge \eta = \eta \wedge \lambda$

◊ **Associativity**

- ◊  $(\lambda \vee \eta) \vee \mu = \lambda \vee (\eta \vee \mu)$

- ◊  $(\lambda \wedge \eta) \wedge \mu = \lambda \wedge (\eta \wedge \mu)$

◊ **Absorption**

- ◊  $\lambda \vee (\lambda \wedge \eta) = \lambda$

- ◊  $\lambda \wedge (\lambda \vee \eta) = \lambda$

◊ **Bounds**

- ◊  $\lambda \vee \mathbf{F} = \lambda$

- ◊  $\lambda \wedge \mathbf{T} = \lambda$

◊ **Distributivity**

- ◊  $\lambda \wedge (\eta \vee \mu) = (\lambda \wedge \eta) \vee (\lambda \wedge \mu)$

- ◊  $\lambda \vee (\eta \wedge \mu) = (\lambda \vee \eta) \wedge (\lambda \vee \mu)$

The operations  $\vee$  and  $\wedge$  induce a natural partial order on  $\mathcal{L}$

$$\lambda \Rightarrow_{\mathcal{L}} \eta \quad \text{iff} \quad \lambda \wedge \eta = \lambda \quad (\text{iff} \quad \lambda \vee \eta = \eta)$$

- ◊ captures implication: whenever  $\lambda$  is true,  $\eta$  is also true
- ◊  $\Rightarrow_{\mathcal{L}}$  is reflexive, antisymmetric, and transitive
- ◊  $F \Rightarrow_{\mathcal{L}} \lambda \Rightarrow_{\mathcal{L}} T$  for all  $\lambda \in \mathcal{L}$

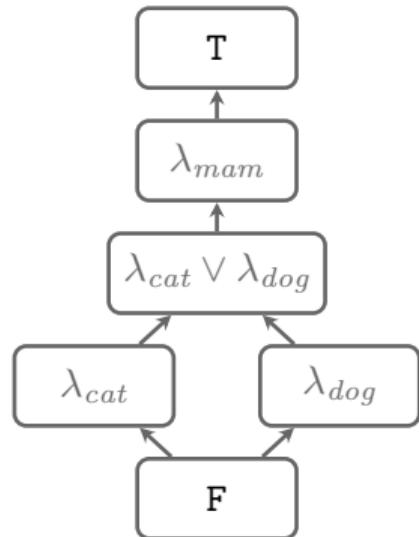

## *Example*

$\mathcal{L}$  is constructed from the primitive statements

- ◊  $\lambda_{cat} = \text{"Martin is a cat"}$
- ◊  $\lambda_{dog} = \text{"Martin is a dog"}$
- ◊  $\lambda_{mam} = \text{"Martin is a mammal"}$

under the axioms / presumption that:

- ◊  $(\lambda_{cat} \wedge \lambda_{dog}) \Rightarrow_{\mathcal{L}} F$ 
  - ◊ It is not possible to be a dog and a cat
- ◊  $(\lambda_{cat} \vee \lambda_{dog}) \Rightarrow_{\mathcal{L}} \lambda_{mam}$ 
  - ◊ If Martin is a dog or is a cat, he is a mammal

A truth assignment for  $\mathcal{L}$  is a function

$$w : \mathcal{L} \rightarrow \{0, 1\}$$

such that for all  $\lambda, \eta \in L$ :

- ◊  $w(\mathbf{T}) = 1$  and  $w(\mathbf{F}) = 0$
- ◊  $w(\lambda \vee \eta) = \max\{w(\lambda), w(\eta)\}$
- ◊  $w(\lambda \wedge \eta) = \min\{w(\lambda), w(\eta)\}$

Truth assignments preserve the implication ordering:

$$\begin{aligned}\lambda \Rightarrow_{\mathcal{L}} \eta &\quad \text{iff} \quad \lambda = \lambda \wedge \eta \\ &\quad \text{iff} \quad w(\lambda) = \min\{w(\lambda), w(\eta)\} \\ &\quad \text{iff} \quad w(\lambda) \leq w(\eta)\end{aligned}$$

Let  $W(\mathcal{L})$  is the set of truth assignments for  $\mathcal{L}$ ;  $W(\mathcal{L})$  is a state-space for  $\mathcal{L}$ :

- ◊ The event corresponding to  $\lambda$  is  $\mathbf{E}(\lambda) = \{w \in W \mid w(\lambda) = 1\}$
- ◊ Implication is containment:  $\lambda \Rightarrow \eta$  if and only if  $\mathbf{E}(\lambda) \subseteq \mathbf{E}(\eta)$
- ◊ Tautology (T) maps to entire state-space, Contradiction (F) to empty-set
- ◊  $\mathbf{E}(\lambda \vee \eta) = \mathbf{E}(\lambda) \cup \mathbf{E}(\eta), \quad \mathbf{E}(\lambda \wedge \eta) = \mathbf{E}(\lambda) \cap \mathbf{E}(\eta)$

*Example*

$\lambda_{cat} = 1$	$\lambda_{dog} = 1$	$\lambda_{mam} = 1$	$\lambda_{cat} = 0$
$\lambda_{mam} = 1$	$\lambda_{mam} = 1$	$\lambda_{cat} = 0$	$\lambda_{dog} = 0$
$\lambda_{dog} = 0$	$\lambda_{cat} = 0$	$\lambda_{dog} = 0$	$\lambda_{mam} = 0$

$w_1^i$

$w_2^i$

$w_3^i$

$w_4$

*Example*

$\lambda_{cat} = 1$	$\lambda_{dog} = 1$	$\lambda_{mam} = 1$	$\lambda_{cat} = 0$
$\lambda_{mam} = 1$	$\lambda_{mam} = 1$	$\lambda_{cat} = 0$	$\lambda_{dog} = 0$
$\lambda_{dog} = 0$	$\lambda_{cat} = 0$	$\lambda_{dog} = 0$	$\lambda_{mam} = 0$

$w_1^i \qquad \qquad w_2^i \qquad \qquad w_3^i \qquad \qquad w_4$

Event  $E(\lambda_{cat})$  = “Martin is a cat”

*Example*

---

$\lambda_{cat} = 1$	$\lambda_{dog} = 1$	$\lambda_{mam} = 1$	$\lambda_{cat} = 0$
$\lambda_{mam} = 1$	$\lambda_{mam} = 1$	$\lambda_{cat} = 0$	$\lambda_{dog} = 0$
$\lambda_{dog} = 0$	$\lambda_{cat} = 0$	$\lambda_{dog} = 0$	$\lambda_{mam} = 0$

$w_1^i \qquad \qquad w_2^i \qquad \qquad w_3^i \qquad \qquad w_4$

Event  $E(\lambda_{mam})$  = “Martin is a mammal”

*Example*

---

$\lambda_{cat} = 1$ $\lambda_{mam} = 1$ $\lambda_{dog} = 0$	$\lambda_{dog} = 1$ $\lambda_{mam} = 1$ $\lambda_{cat} = 0$	$\lambda_{mam} = 1$ $\lambda_{cat} = 0$ $\lambda_{dog} = 0$	$\lambda_{cat} = 0$ $\lambda_{dog} = 0$ $\lambda_{mam} = 0$
$w_1^i$	$w_2^i$	$w_3^i$	$w_4$

$E(\lambda_{cat}) \subseteq E(\lambda_{mam})$ , cat implies mammal

*Model: Translation*

There are two agents, 1 and 2, each endowed with a language  $\mathcal{L}_1$  and  $\mathcal{L}_2$

- ◊ let  $\Rightarrow_i$  denote implication in  $i$ 's language
- ◊ let  $\mathbf{T}_i$  and  $\mathbf{F}_i$  denote the tautology and contradiction
- ◊ A translation operator (from  $i$  to  $j$ ) is a function from  $i$ 's language to  $j$ 's

*Example*

Consider a Spanish speaker,  $\mathcal{L}_j$ , who is never heard of ‘mammals’

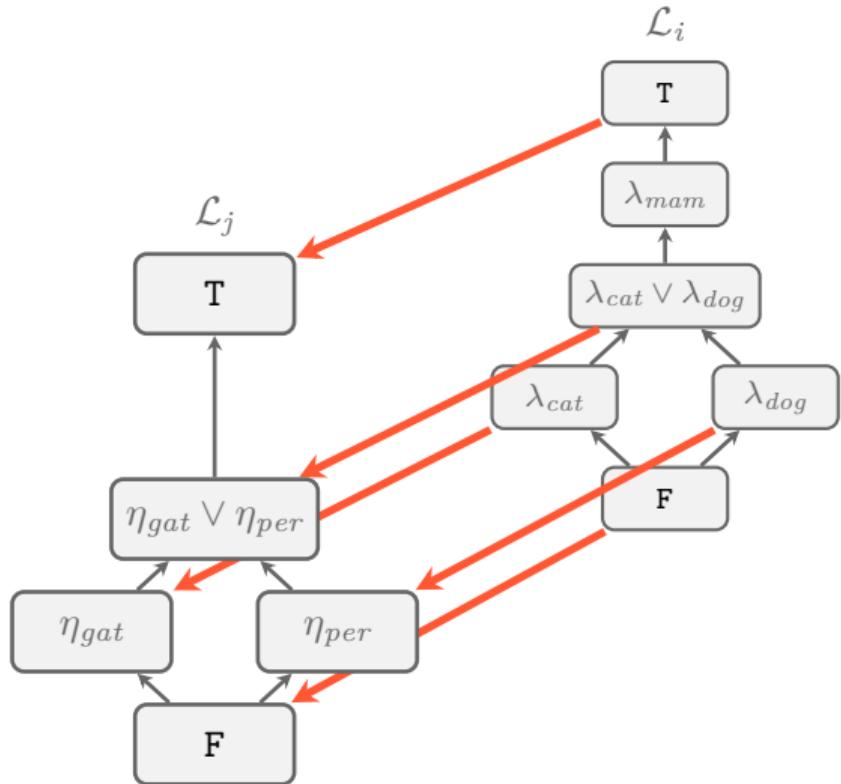

- ◊  $\eta_{gat} = \text{“Martin es un gato”}$
- ◊  $\eta_{per} = \text{“Martin es un perro”}$

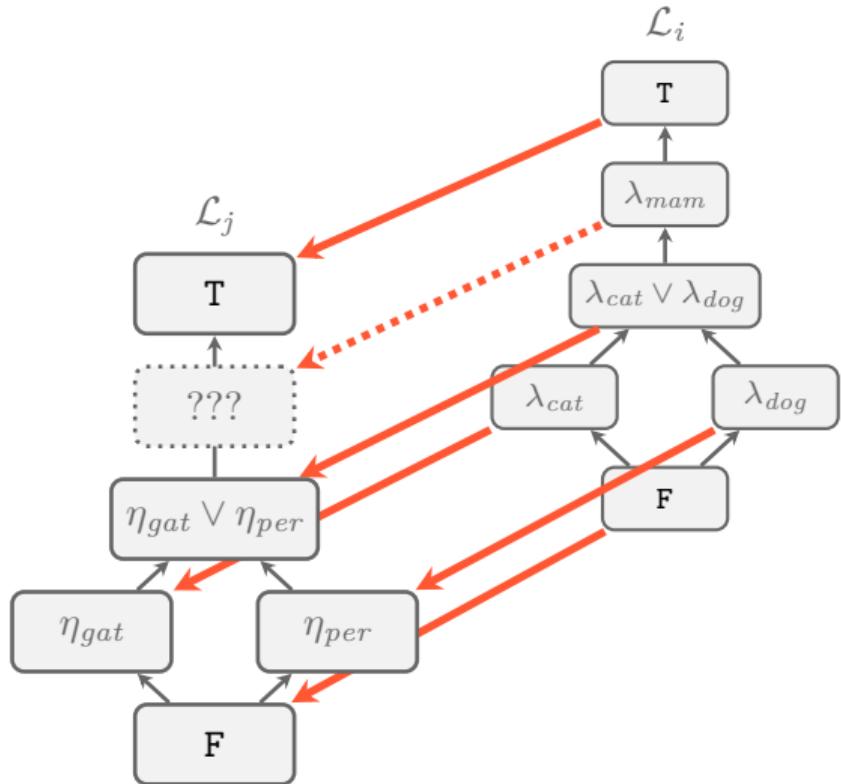

$\eta_{gat} = 1$	$\eta_{per} = 1$	$\eta_{gat} = 0$
$\eta_{per} = 0$	$\eta_{gat} = 0$	$\eta_{per} = 0$

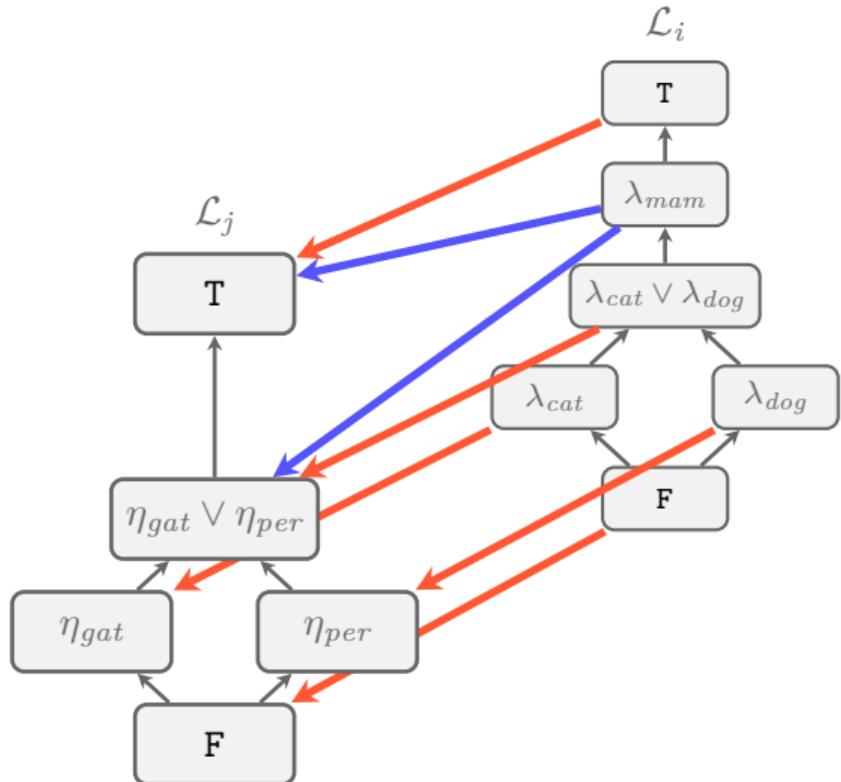

$\hat{w}_1$

$\hat{w}_2$

$\hat{w}_3$

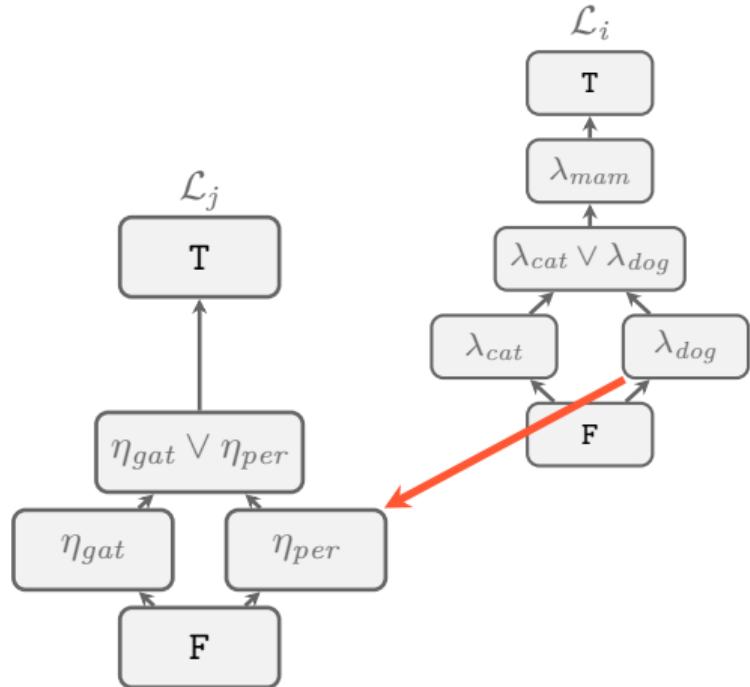

We consider two kinds of translations

- ◊ Inner Translation operator  $T_{i \rightarrow j}^-$ 
  - ◊ From ‘below’
  - ◊ Provides a *more specific* approximation
- ◊ Outer Translation operator  $T_{i \rightarrow j}^+$ 
  - ◊ From ‘above’
  - ◊ Provides a *more general* approximation

Translation of  $\lambda_{dog}$

$$T_{i \rightarrow j}^-(\lambda_{dog}) = \eta_{per} = T_{i \rightarrow j}^+(\lambda_{dog})$$

- ◊ No gap between  $T_{i \rightarrow j}^-$  and  $T_{i \rightarrow j}^+$
- ◊ This is a ‘perfect’ translation

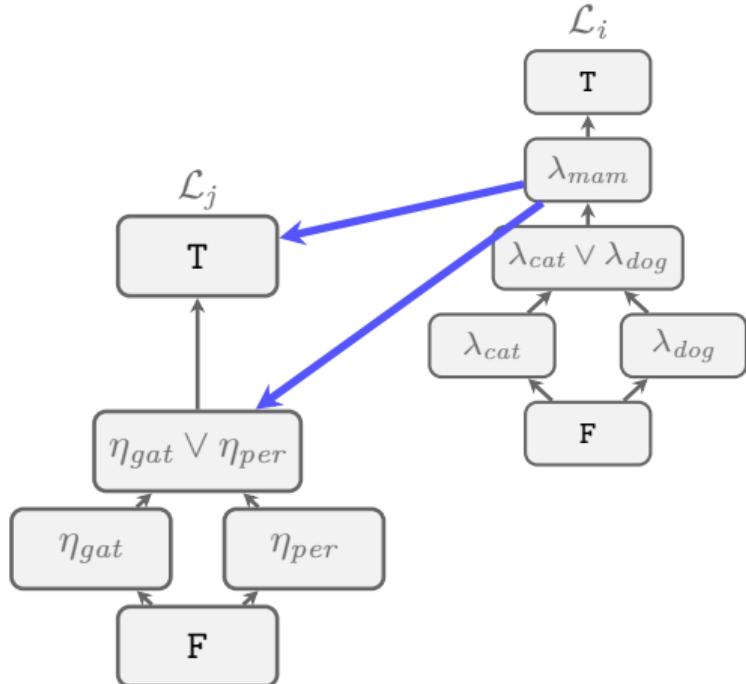

Translation of  $\lambda_{mam}$

- ◊  $j$  has never heard of a mammals,
- ◊ no statement captures it exactly
- ◊ All cats and dogs are mammals:

$$\mathsf{T}_{i \rightarrow j}^-(\lambda_{mam}) = (\eta_{gat} \vee \eta_{per})$$

- ◊ All mammals are something:

$$\mathsf{T}_{i \rightarrow j}^+(\lambda_{mam}) = \mathbf{T}_j$$

Consider a set of ‘translation’ operators

$$T = \langle T_{1 \rightarrow 2}^-, T_{1 \rightarrow 2}^+, T_{2 \rightarrow 1}^-, T_{2 \rightarrow 1}^+ \rangle$$

When does  $T$  behave like a translation?

- ◊ serves as the ‘best approximations’
- ◊ preserves logical structure

For a (complete) distributive lattice, ‘best approximations’ would mean

$$T_{i \rightarrow j}^-(\lambda_i) = \bigvee \{\eta_j \in \mathcal{L}_j \mid \eta_j \text{ implies } \lambda_i\}$$

$$T_{i \rightarrow j}^+(\lambda_i) = \bigwedge \{\eta_j \in \mathcal{L}_j \mid \lambda_i \text{ implies } \eta_j\}$$

Two issues:

1. What does it mean for  $\eta_j$  to imply  $\lambda_i$ ?
2. Infinite joins / meets might not exist

# *Cross Language Implication*

- ◊ *j* is trying to ascertain whether *perro* (dog) implies *mammal*.
  - ◊ *j* could point to various *perros*
  - ◊ *i* affirm that these are all also *mammals*
  - ◊ exhibits the implication holds
- ◊ now *i* is trying to ascertain whether *mammal* implies *perro*:
  - ◊ *i* could point to various *mammals*
  - ◊ when pointing at a *cat*, *j* can deny that it is a *mammal*
  - ◊ refutes the implication holds

Consider a binary relation  $\Rightarrow^*$  over  $\mathcal{L}_i \cup \mathcal{L}_j$

- ◊ represents when one statement implies another, *across languages*
- ◊ this is, in principle, observable to some outside modeler (as above)
- ◊  $\Rightarrow^*$  must satisfy some consistency properties to maintain the logic of distributive lattices

## I1: Within Language Consistency

For all  $\lambda_i, \lambda'_i \in \mathcal{L}_i$ :

$$\lambda_i \Rightarrow^* \lambda'_i \quad \text{if and only if} \quad \lambda_i \Rightarrow_i \lambda'_i.$$

I2: Transitivity

$\Rightarrow^*$  is transitive

### I3: Connective Consistency

Let  $\eta_j, \eta'_j \in \mathcal{L}_j$  and  $\lambda_i \in \mathcal{L}_i$ . Then:

(i)  $\lambda_i \Rightarrow^* \eta_j$  and  $\lambda_i \Rightarrow^* \eta'_j$  implies  $\lambda_i \Rightarrow^* (\eta_j \wedge \eta'_j)$

(ii)  $\eta_j \Rightarrow^* \lambda_i$  and  $\eta'_j \Rightarrow^* \lambda_i$  implies  $(\eta_j \wedge \eta'_j) \Rightarrow^* \lambda_i$

- \* if you have a complete lattice, you could ask for arbitrary meets/joins

#### I4: Principle of Explosion

For all  $\lambda_j \in \mathcal{L}_j$ ,

$$f_i \Rightarrow^* \lambda_j$$

Given a (complete) lattice, if  $\Rightarrow^*$  satisfies I1-I4, then

$$\tau_{i \rightarrow j}^-(\lambda_i) = \bigvee \{\eta_j \in \mathcal{L}_j \mid \eta_j \Rightarrow^* \lambda_i\}$$

$$\tau_{i \rightarrow j}^+(\lambda_i) = \bigwedge \{\eta_j \in \mathcal{L}_j \mid \lambda_i \Rightarrow^* \eta_j\}$$

is well defined.

Given a (complete) lattice, if  $\Rightarrow^*$  satisfies I1-I4, then

$$\text{T}_{i \rightarrow j}^-(\lambda_i) = \bigvee \{\eta_j \in \mathcal{L}_j \mid \eta_j \Rightarrow^* \lambda_i\}$$

$$\text{T}_{i \rightarrow j}^+(\lambda_i) = \bigwedge \{\eta_j \in \mathcal{L}_j \mid \lambda_i \Rightarrow^* \eta_j\}$$

is well defined. However,

$$\{\eta_j \in \mathcal{L}_j \mid \lambda_i \Rightarrow^* \eta_j\}$$

might be empty.

Given a (complete) lattice, if  $\Rightarrow^*$  satisfies I1-I4, then

$$T_{i \rightarrow j}^-(\lambda_i) = \bigvee \{\eta_j \in \mathcal{L}_j \mid \eta_j \Rightarrow^* \lambda_i\} \in \mathcal{L}_j$$

$$T_{i \rightarrow j}^+(\lambda_i) = \bigwedge \{\eta_j \in \mathcal{L}_j \mid \lambda_i \Rightarrow^* \eta_j\} \in \mathcal{L}_j \cup \{*\}$$

is well defined. However,

$$\{\eta_j \in \mathcal{L}_j \mid \lambda_i \Rightarrow^* \eta_j\}$$

might be empty. Define  $\bigwedge \emptyset = *$ .

*Example*

$\mathcal{L}_1$

---

$\lambda_{egg}$  = “*Tonya* lays eggs”

$\lambda_{mam}$  = “*Tonya* is a mammal”

$\lambda_{plat}$  = “*Tonya* is a platypus”

$\mathcal{L}_2$

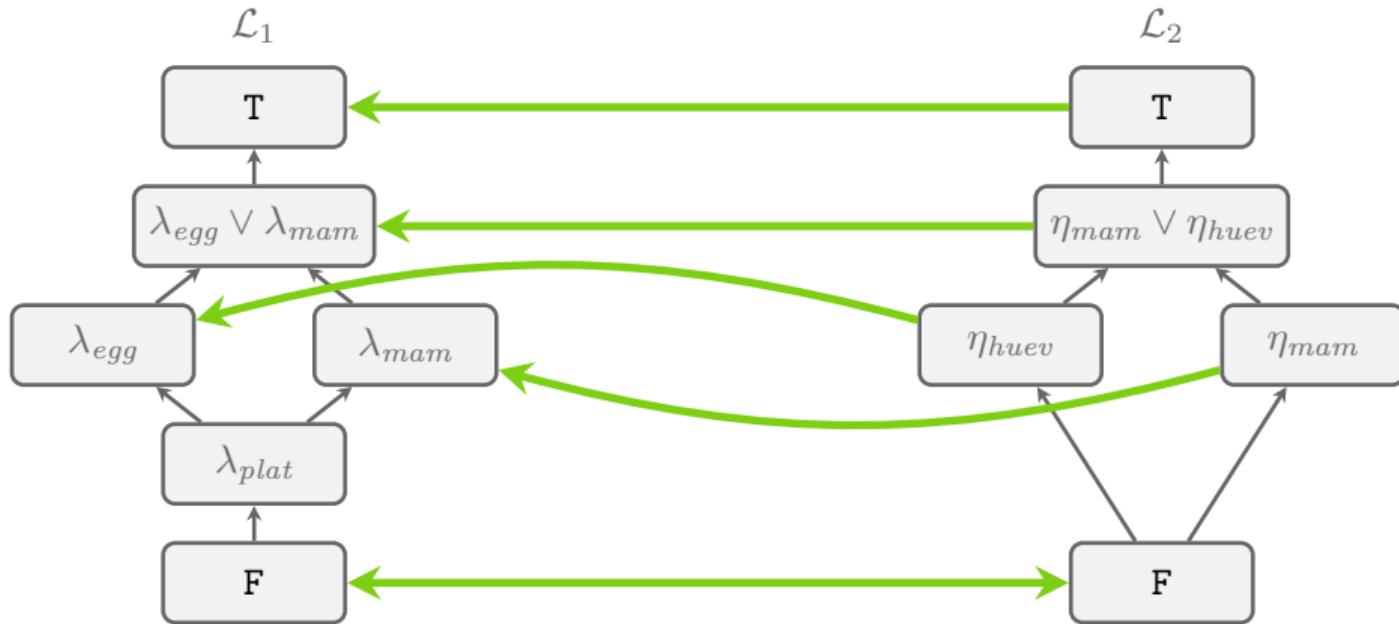

---

$\eta_{huev}$  = “*Tonya* pone huevos”

$\eta_{mam}$  = “*Tonya* es un mamífero”

- ◊ 1 is aware of platypus, so  $(\lambda_{egg} \wedge \lambda_{mam}) \Rightarrow_1 \lambda_{plat}$
- ◊ 2 is not aware of platypus, so  $(\eta_{huev} \wedge \eta_{mam}) \Rightarrow_2 f_2$

The additional components of  $\Rightarrow^*$ :

*Example*

How should we translate  $\lambda_{mam}$  from  $1 \rightarrow 2$ ?

- ◊  $\eta_{mam}$  is more specific than  $\lambda_{mam}$ , so  $T_{1 \rightarrow 2}^-(\lambda_{mam}) = \eta_{mam}$  makes sense
- ◊ But there is *no* element in  $\mathcal{L}_2$  more general
  - ◊ Nothing in 2's language allows for platypus
- ◊ So, we can set  $T_{1 \rightarrow 2}^+(\lambda_{mam}) = *$
- ◊ \* represents the inclusion of something the target language is unaware of

# *Abstract Translation*

We can return to our original question: given

$$T = \langle T_{1 \rightarrow 2}^-, T_{1 \rightarrow 2}^+, T_{2 \rightarrow 1}^-, T_{2 \rightarrow 1}^+ \rangle$$

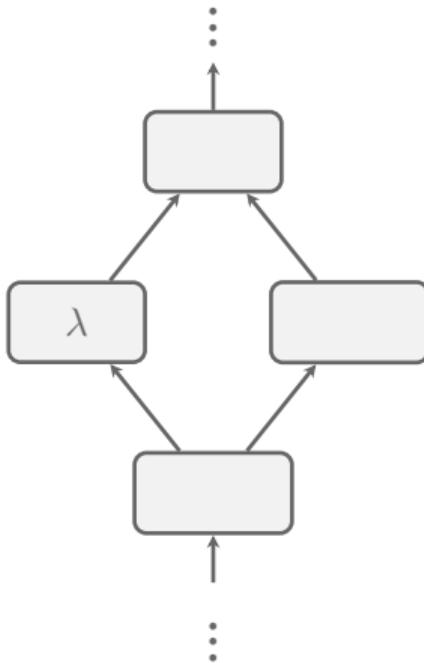

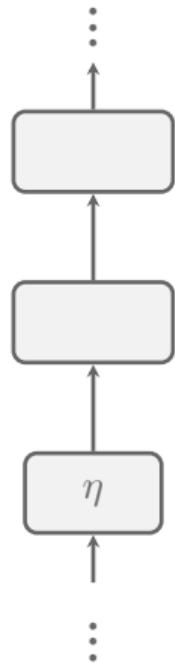

When does  $T$  behave like a translation?

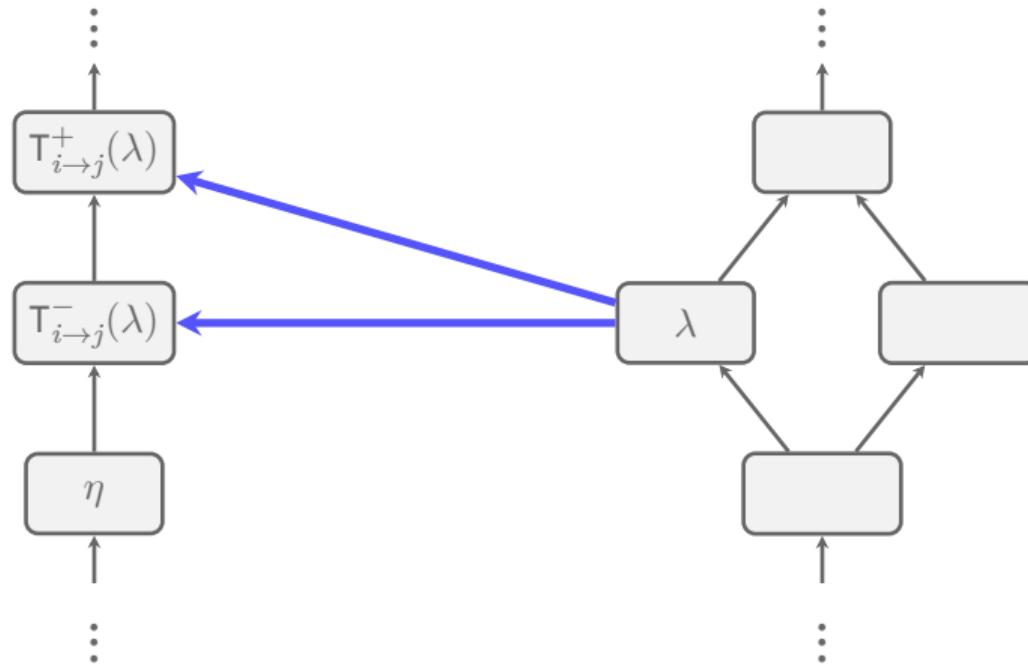

- ◊ Each  $T_{i \rightarrow j} : \mathcal{L}_i \rightarrow \mathcal{L}_j^*$  (where  $\mathcal{L}_j^* = \mathcal{L}_j \cup \{*\}$ )
- ◊ We require two axioms on  $T$

### C1: Galois

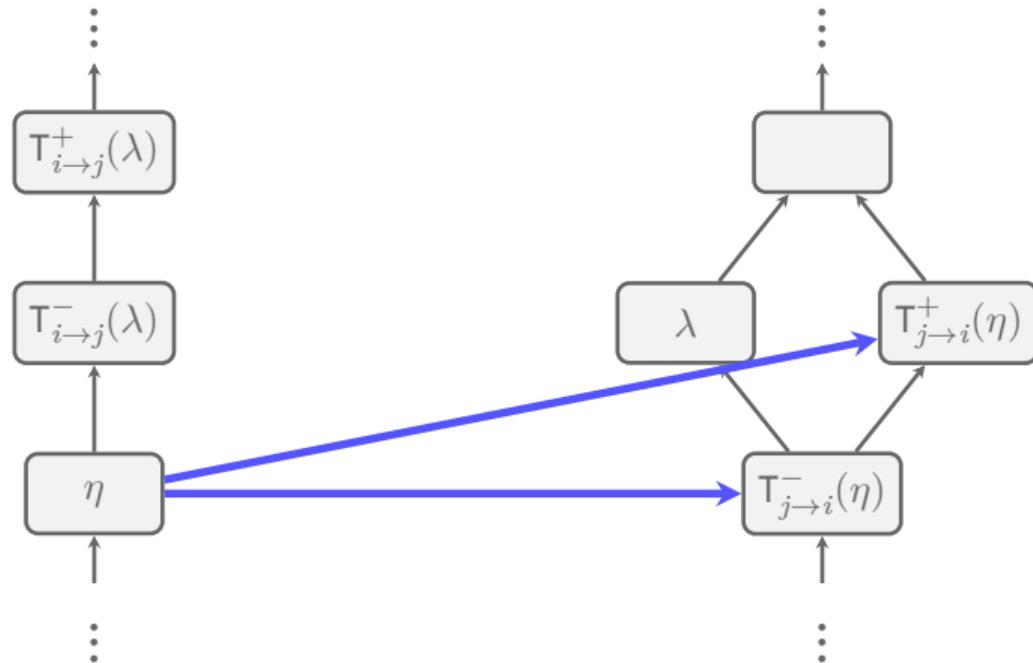

For all  $\lambda \in \mathcal{L}_i^*$  and  $\eta \in \mathcal{L}_j^*$ :

$$\eta \Rightarrow_j T_{i \rightarrow j}^-(\lambda) \quad \text{if and only if} \quad T_{j \rightarrow i}^+(\eta) \Rightarrow_i \lambda.$$

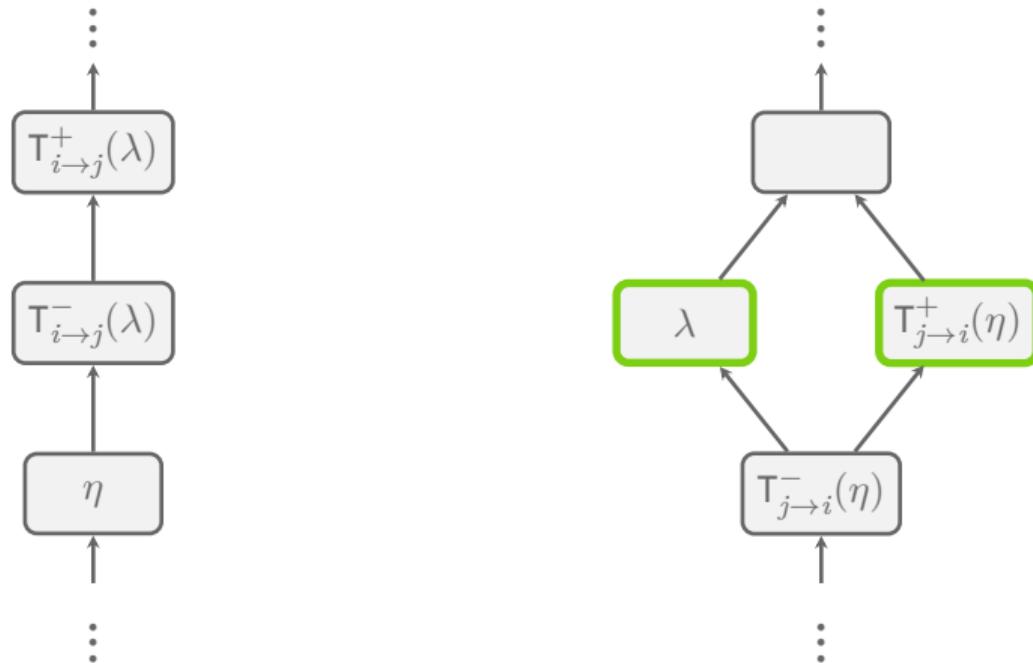

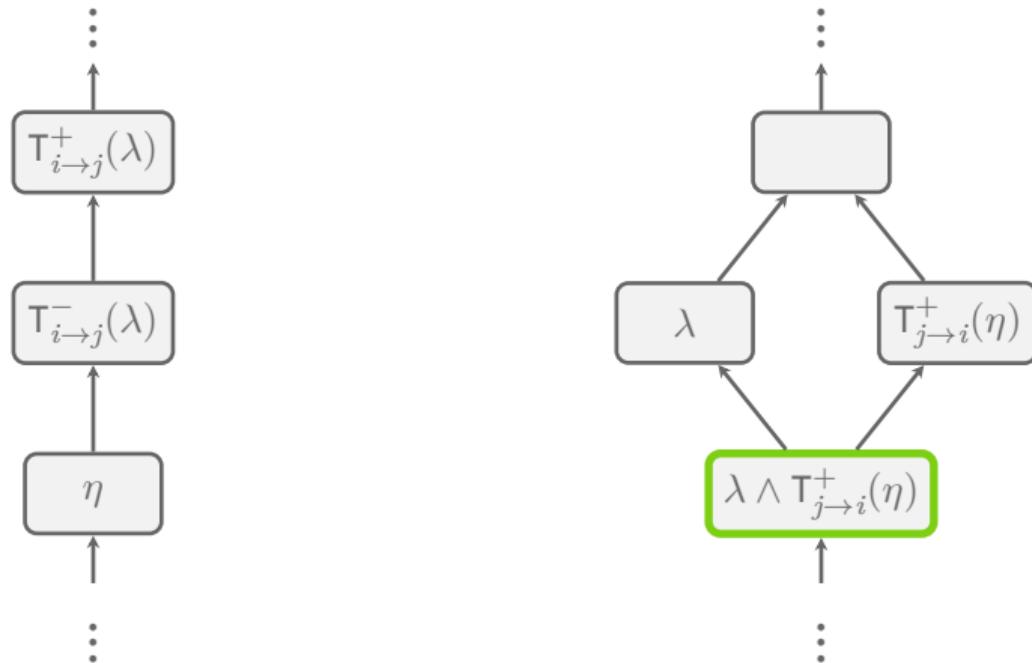

$\eta \Rightarrow_j T_{i \rightarrow j}^-(\lambda)$ ; thus  $\lambda$  is more general than  $\eta$

If  $T$  violates C1 then  $T_{j \rightarrow i}^+(\eta) \not\sim_i \lambda$

So both  $\lambda$  and  $T_{j \rightarrow i}^+(\eta)$  are more general than  $\eta$

Then  $\lambda \wedge T_{j \rightarrow i}^+(\eta)$  is *better* approximation of  $\eta$  from above

## C2: Monotone Approximation

For all  $\lambda_i \in \mathcal{L}_i^*$  we have  $T_{i \rightarrow j}^-(\lambda_i) \Rightarrow_j T_{i \rightarrow j}^+(\lambda_i)$ .

- ◊ The inner translation should be more specific than the outer translation

## Theorem

The following are equivalent:

(1)  $T$  satisfies C1 and C2

(2) There exists a (unique)  $\Rightarrow^*$  satisfying I1–I4 such that<sup>1</sup>

$$\eta_j \Rightarrow^* \lambda_i \quad \text{if and only if} \quad \eta_j \Rightarrow_j T_{i \rightarrow j}^-(\lambda_i), \quad \text{and} \quad (\star^-)$$

$$\lambda_i \Rightarrow^* \eta_j \quad \text{if and only if} \quad T_{i \rightarrow j}^+(\lambda_i) \Rightarrow_j \eta_j \quad (\star^+)$$

---

<sup>1</sup>Where  $\lambda \Rightarrow_i *$  and  $* \not\Rightarrow_i \lambda$  for all  $\lambda \in \mathcal{L}_i$

**C1** is abstract in nature, we can characterize it via ‘structural’ properties

**T1.**  $\mathsf{T}^-$  and  $\mathsf{T}^+$  preserve contradiction:

$$\mathsf{T}_{i \rightarrow j}^-(f_i) = \mathsf{T}_{i \rightarrow j}^+(f_i) = f_j$$

**T2.**  $\mathsf{T}^-$  and  $\mathsf{T}^+$  preserves implication:

$$\lambda \Rightarrow_i \lambda' \text{ implies } \begin{cases} \mathsf{T}_{i \rightarrow j}^-(\lambda) \Rightarrow_j \mathsf{T}_{i \rightarrow j}^-(\lambda') \text{ and} \\ \mathsf{T}_{i \rightarrow j}^+(\lambda) \Rightarrow_j \mathsf{T}_{i \rightarrow j}^+(\lambda') \end{cases}$$

**T3.**  $\mathsf{T}_{i \rightarrow j}^-$  preserves conjunction:

$$\mathsf{T}_{i \rightarrow j}^-(\lambda \wedge \lambda') = \mathsf{T}_{i \rightarrow j}^-(\lambda) \wedge \mathsf{T}_{i \rightarrow j}^-(\lambda')$$

**T4.**  $\mathsf{T}_{i \rightarrow j}^+$  preserves disjunction:

$$\mathsf{T}_{i \rightarrow j}^+(\lambda \vee \lambda') = \mathsf{T}_{i \rightarrow j}^+(\lambda) \vee \mathsf{T}_{i \rightarrow j}^+(\lambda')$$

- ◊  $W(\mathcal{L}_i)$  and  $W(\mathcal{L}_j)$  act as ‘local’ state-spaces
- ◊ If  $W^*$  is some ‘global’ state-space that nests both:
  - ◊ Then translation operators appear as inner and outer approximation
  - ◊ As in measure theory, etc

*Example*

$\lambda_{cat} = 1$ $\lambda_{mam} = 1$ $\eta_{gat} = 1$ $\lambda_{dog} = 0$ $\eta_{per} = 0$	$\lambda_{dog} = 1$ $\lambda_{mam} = 1$ $\eta_{per} = 1$ $\lambda_{cat} = 0$ $\eta_{gat} = 0$	$\lambda_{mam} = 1$ $\lambda_{cat} = 0$ $\lambda_{dog} = 0$ $\eta_{gat} = 0$ $\eta_{per} = 0$	$\lambda_{cat} = 0$ $\lambda_{dog} = 0$ $\lambda_{mam} = 0$ $\eta_{gat} = 0$ $\eta_{per} = 0$
$\eta_{gat} = 1$ $\eta_{per} = 0$	$\eta_{per} = 1$ $\eta_{gat} = 0$		$\eta_{gat} = 0$ $\eta_{per} = 0$

*Example*

$\lambda_{cat} = 1$ $\lambda_{mam} = 1$ $\eta_{gat} = 1$ $\lambda_{dog} = 0$ $\eta_{per} = 0$	$\lambda_{dog} = 1$ $\lambda_{mam} = 1$ $\eta_{per} = 1$ $\lambda_{cat} = 0$ $\eta_{gat} = 0$	$\lambda_{mam} = 1$ $\lambda_{cat} = 0$ $\lambda_{dog} = 0$ $\eta_{gat} = 0$ $\eta_{per} = 0$	$\lambda_{cat} = 0$ $\lambda_{dog} = 0$ $\lambda_{mam} = 0$ $\eta_{gat} = 0$ $\eta_{per} = 0$
$\eta_{gat} = 1$ $\eta_{per} = 0$	$\eta_{per} = 1$ $\eta_{gat} = 0$		$\eta_{gat} = 0$ $\eta_{per} = 0$

*Example*

$W^*$	$\lambda_{cat} = 1$	$\lambda_{dog} = 1$	$\lambda_{mam} = 1$	$\lambda_{cat} = 0$
	$\lambda_{mam} = 1$	$\lambda_{mam} = 1$	$\lambda_{cat} = 0$	$\lambda_{dog} = 0$
	$\eta_{gat} = 1$	$\eta_{per} = 1$	$\lambda_{dog} = 0$	$\lambda_{mam} = 0$
	$\lambda_{dog} = 0$	$\lambda_{cat} = 0$	$\eta_{gat} = 0$	$\eta_{gat} = 0$
	$\eta_{per} = 0$	$\eta_{gat} = 0$	$\eta_{per} = 0$	$\eta_{per} = 0$

Does such a state-space  $W^*$  always exist?

*Example*

---

$\mathcal{L}_1$

$\lambda = \text{"God exists"}$

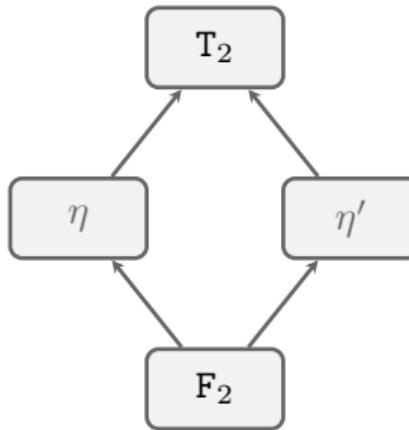

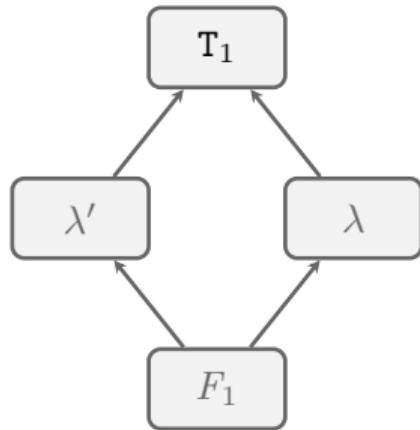

$\lambda' = \text{"God does not exist"}$

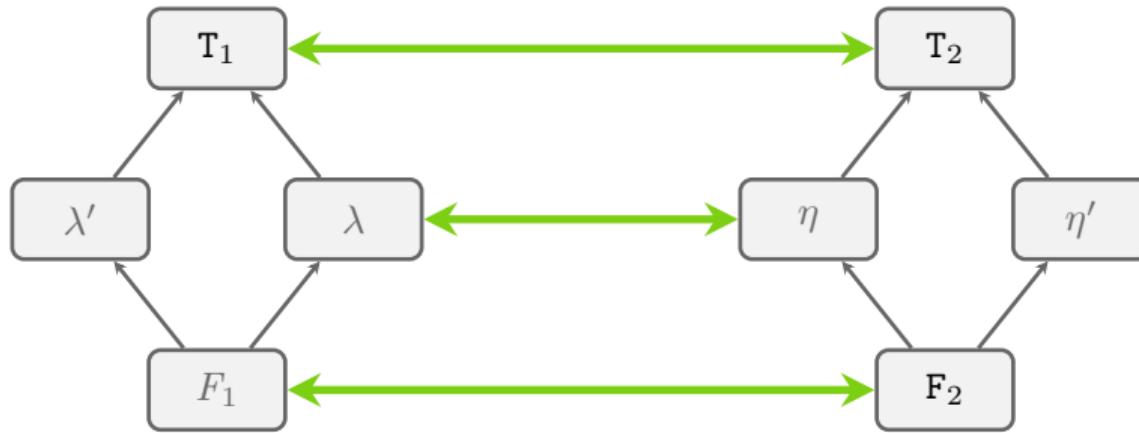

$\mathcal{L}_2$

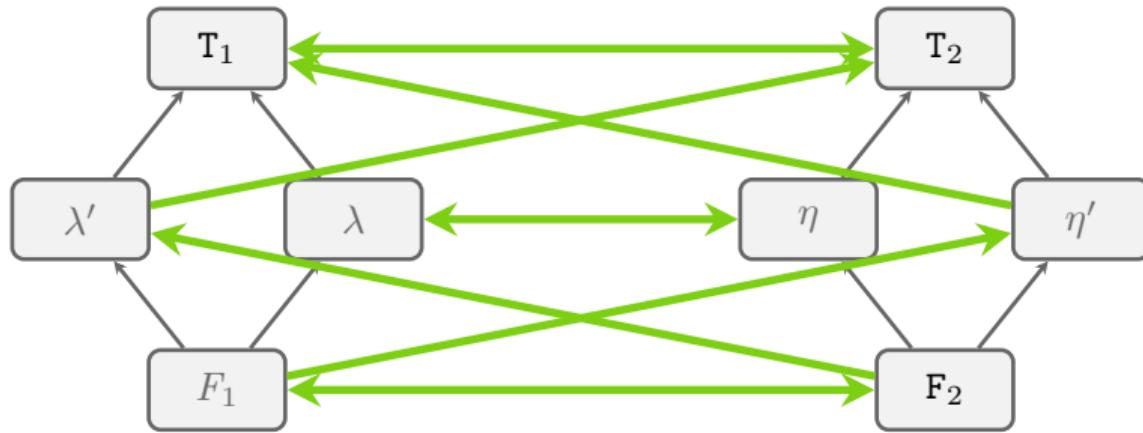

$\eta = \text{"Dios es bueno"}$

$\eta' = \text{"Dios es malvado"}$

- ◊ 1 cannot conceive of an evil God, but is unsure a benevolent God exists
  - ◊  $T_1 \Rightarrow_1 (\lambda \vee \lambda'), (\lambda \wedge \lambda') \Rightarrow_1 F_1$
- ◊ 2 defines God as what is in the universe, but is unsure its moral character
  - ◊  $T_2 \Rightarrow_2 (\eta \vee \eta'), (\eta \wedge \eta') \Rightarrow_2 F_2$

*Example*

$\mathcal{L}_i$

$\mathcal{L}_j$

---

$\lambda$  = “God exists”

$\eta$  = “Dios es bueno”

$\lambda'$  = “God does not exist”

$\eta'$  = “Dios es malvado”

$$\mathsf{T}_{1 \rightarrow 2}^-(f_i) = f_j$$

$$\mathsf{T}_{1 \rightarrow 2}^+(f_i) = f_j$$

$$\mathsf{T}_{1 \rightarrow 2}^-(\lambda) = \eta$$

$$\mathsf{T}_{1 \rightarrow 2}^+(\lambda) = \eta$$

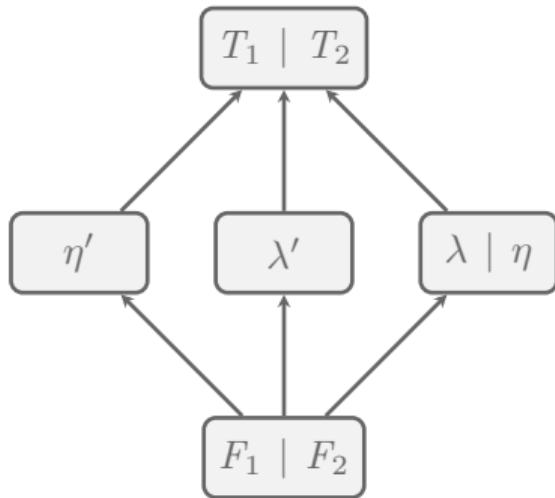

$$\mathsf{T}_{1 \rightarrow 2}^-(\lambda') = f_j$$

$$\mathsf{T}_{1 \rightarrow 2}^+(\lambda') = t_j$$

$$\mathsf{T}_{1 \rightarrow 2}^-(t_i) = t_j$$

$$\mathsf{T}_{1 \rightarrow 2}^+(t_i) = t_j$$

This satisfies our axioms but admits no state-space representation. The induced graph, i.e.,  $(\mathcal{L}_i \cup \mathcal{L}_j) / \Rightarrow^*$ :

is not distributive.

Open question:

what additional axioms does  $T$  (equivalently,  $\Rightarrow^*$ ) need to satisfy to ensure existence of state-space representation?

We can answer this for Boolean languages:

- ◊ Assume  $\mathcal{L}_i$  and  $\mathcal{L}_j$  are Boolean algebras
- ◊ Closed under *negation*: if  $\lambda \in \mathcal{L}$  then  $\neg\lambda \in \mathcal{L}$ :
  - ◊  $\lambda \wedge \neg\lambda = \mathbf{F}$ ,
  - ◊  $\lambda \vee \neg\lambda = \mathbf{T}$

### C3: Duality

For  $\lambda_i \in \mathcal{L}_i$  and  $\eta_j \in \mathcal{L}_j$  such that  $T_{i \rightarrow j}^+(\lambda_i) \neq *$ :

$$T_{i \rightarrow j}^-(\neg \lambda_i) = \neg T_{i \rightarrow j}^+(\lambda_i) \wedge T_{i \rightarrow j}^-(T_i).$$

If agents share a view of truth:  $T_{i \rightarrow j}^-(T_i) = T_j = T_{i \rightarrow j}^+(\lambda_i)$  then we can simplify:

$$T_{i \rightarrow j}^-(\neg \lambda_i) = \neg T_{i \rightarrow j}^+(\lambda_i),$$

for all statements.

## I5: Negation Consistency

For  $\lambda_i \in \mathcal{L}_i$  and  $\eta_j \in \mathcal{L}_j$  such that  $\lambda_i \rightarrow^* T_j$ :

$$\eta_j \Rightarrow^* \neg \lambda_i \quad \text{implies} \quad \lambda_i \Rightarrow^* \neg \eta_j.$$

## Theorem

The following are equivalent:

- (1)  $T$  satisfies C1-3
- (2) There exists a (unique)  $\Rightarrow^*$  satisfying I1-5 that defines it (via  $\star^-$  and  $\star^+$ ).
- (3) There exists a joint state-space representation of  $\mathcal{L}_i$  and  $\mathcal{L}_j$ :

State-space is 'locally' Boolean

- ◊  $\wedge$  and  $\vee$  map to  $\cap$  and  $\cup$ , respectively
- ◊  $F$  maps to  $\emptyset$
- ◊  $\neg$  maps to *relative complementation* w.r.t.  $T$

*Thank You*
